**Abstract.** The MEM mode is a nonce-based enciphering mode of operation proposed by Chakraborty and Sarkar, which was claimed to be secure against symmetric nonce respecting adversaries. We show that this is not correct by using two very simple attacks. One attack needs one decryption and one decryption queries, and the other only needs one encryption query.

**Keywords.** Blockcipher, tweakable blockcipher, modes of operation, nonce-based encryption.

## 1 Introduction

A *mode of operation*, or mode, for short, is a scheme that specifies how to use a *blockcipher* to provide some cryptographic services, such as privacy or authenticity. Recently, Chakraborty and Sarkar proposed the MEM (Mask Encrypt Mask) mode, a *nonce-based* enciphering, or length preserving encryption, mode of operation which was claimed to be secure against *symmetric nonce respecting* adversaries.

Suppose the underlying blockcipher is

$$E : \mathcal{K} \times \{0, 1\}^n \rightarrow \{0, 1\}^n$$

where  $\mathcal{K}$  is a key space, then the MEM mode is

$$\text{MEM}[E] : \mathcal{K} \times \mathcal{N} \times (\{0, 1\}^n)^+ \rightarrow (\{0, 1\}^n)^+$$

where  $\mathcal{N} = \{0, 1\}^n$  is a nonce space and the key space  $\mathcal{K}$  is same as that of the underlying blockcipher  $E$ . Let  $\mathbf{E}_K(\cdot, \cdot)$  and  $\mathbf{D}_K(\cdot, \cdot)$  be the encryption and the decryption algorithms of MEM respectively, and let  $D_K$  be the inverse of  $E_K$ .

**Symmetric Nonce Respecting Adversaries.** The nonce-based encryption is a syntax for an encryption scheme where the encryption process is a deterministic algorithm which surfaces an initial vector. This syntax was advocated by Rogaway, Bellare, *et al.* [RBBK01,Rog04b], and first used in the OCB

mode [RBBK01,Rog04a], then adopted by the GCM mode [MV02], the CWC mode [KVW04], the EAX mode [BRW04], etc.

The security model of MEM assumes that the adversary be symmetric nonce respecting, i.e., the adversary can not repeat nonce in either encryption or decryption query. Note that an adversary is allowed to choose the same nonce for both the encryption and the decryption queries. Without loss generality, we also assume that the adversary does not make *pointless* query, such as a decryption query of  $(N, C)$  after get it as an answer to an encryption query, etc. To sum up, the disallowed queries for the symmetric nonce respecting adversaries are listed below:

When query	and get	then these queries are disallowed:
$\mathbf{E}_K(N, P)$	$C$	$\mathbf{E}_K(N, \cdot), \mathbf{D}_K(N, C)$
$\mathbf{D}_K(N, C)$	$P$	$\mathbf{D}_K(N, \cdot), \mathbf{E}_K(N, P)$

Symmetric nonce respecting model is a reasonable in certain scenarios [CS06]. Get rid of the nonce respecting restriction, the security mode is exactly that of strong secure *tweakable blockcipher* [LRW02]. Dedicated strong secure tweakable blockcipher constructions, such as CMC [HR03], EME [HR04], HCTR [WFW05], etc. are of course secure against symmetric nonce respecting adversaries.

**Security Claimed by [CS06].** Chakraborty, *et al.* claimed that the symmetric nonce respecting adversary cannot distinguish the output of  $\mathbf{E}_K(\cdot, \cdot)$  and  $\mathbf{D}_K(\cdot, \cdot)$  from that of a *random tweakable permutation* and its inverse; Or equivalently saying [CS06,HR03,HR04], this kind of adversary cannot distinguish the output of  $\mathbf{E}_K(\cdot, \cdot)$  and  $\mathbf{D}_K(\cdot, \cdot)$  from that of  $\$(\cdot, \cdot)$  and  $\$(\cdot, \cdot)$ , where  $\$(N, P)$  returns a random string of length  $|P|$ . Let  $\approx$  denote the indistinguishability. They “proved” that:

$$\mathbf{E}_K(\cdot, \cdot), \mathbf{D}_K(\cdot, \cdot) \approx \$(\cdot, \cdot), \$(\cdot, \cdot).$$

The security proof is always a subtle thing, especial a long one. For example, the EMD mode [Rog02] proposed by Rogaway also had a proof, but was soon broken by Joux [Jou03].

**Our Contributions.** We show that EME is not secure against symmetric nonce respecting adversaries at all. The first attack makes one decryption and one encryption queries. The second attack makes only one encryption query.

## 2 Specifications of MEM

An  $n$ -bit string is viewed as an element in the finite field  $GF(2)[x]/\tau(x)$ , where  $\tau(x)$  is a fixed irreducible polynomial of degree  $n$ .

MEM makes use of the polynomials  $p_i(x)$  which are defined as following. For  $0 < i < m$  and  $(n + 1) \nmid i$ , define  $p_i(x) = x^{j-1} + x^j$ , where  $j = (i - 1)$

mod  $(n + 1) + 1$ ; for  $0 < i < m$  and  $(n + 1) \mid i$ , define  $p_i(x) = x^n + 1$ ; for  $i = m$ , define  $p_i = x^{j-1} + 1$ , where  $j = (i - 1) \bmod (n + 1) + 1$ .

The encryption and decryption algorithms of EME are listed in the figure 1, which consists of three cases:  $m = 1$ ,  $m = 2$  and  $m > 2$ . In our attacks we only make use of the case  $m > 2$ . Figure 2 shows the enciphering of a four-block message.

---	---

**Fig. 1.** The MEM Mode

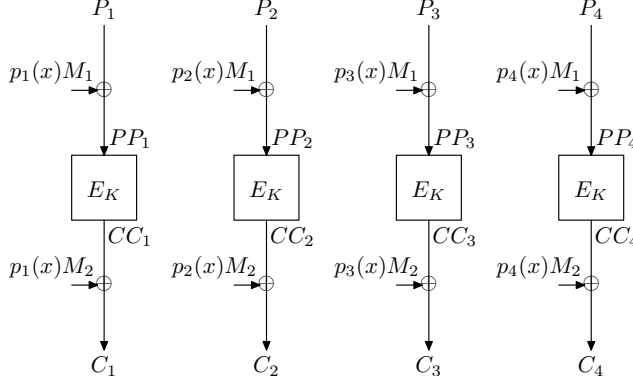

### 3 Distinguishers against MEM

We can distinguish  $E_K(\cdot, \cdot)$ ,  $D_K(\cdot, \cdot)$  from  $\$(\cdot, \cdot)$ ,  $\$(\cdot, \cdot)$  with overwhelming advantage of  $1 - 1/2^n$ . The first distinguisher makes one decryption and one encryption queries. The second distinguisher makes only one encryption.

#### 3.1 Two-query Distinguisher

This distinguisher is similar to the one used in [CS06] to show that MEM is not secure against nonce repeating adversary. The difference is that the one in [CS06] made two encryption queries with the same nonce and we make one decryption and one encryption queries with the same nonce.

The distinguisher is as following:

**Fig. 2.** Enciphering a four-block message  $P_1P_2P_3P_4$  under MEM. Set  $M_1 = E_K(P_1 \oplus P_2 \oplus P_3 \oplus P_4 \oplus E_K(N))$  and  $M_2 = E_K(CC_1 \oplus CC_2 \oplus CC_3 \oplus CC_4 \oplus E_K(xE_K(N)))$ .

1. Make a decryption query  $(N^s, C_1^s, C_2^s, C_3^s, C_4^s)$  and get  $(P_1^s, P_2^s, P_3^s, P_4^s)$ ;
2. Make an encryption query  $(N^t, P_1^t, P_2^t, P_3^t, P_4^t)$  and get  $(C_1^t, C_2^t, C_3^t, C_4^t)$ , where  $N^s = N^t$ ,  $P_1^s = P_1^t$ ,  $P_2^s = P_2^t$ ,  $P_3^s \neq P_3^t$ , and  $P_3^s \oplus P_4^s = P_3^t \oplus P_4^t$ .
3. Calculate  $X_1 = p_1(x)^{-1}(C_1^s \oplus C_1^t)$  and  $X_2 = p_2(x)^{-1}(C_2^s \oplus C_2^t)$ .
4. If  $X_1 = X_2$ , then return 1, else return 0.

When the distinguisher queries  $\mathbf{E}_K(\cdot, \cdot)$ ,  $\mathbf{D}_K(\cdot, \cdot)$ ,

$$M_2^s = p_1(x)^{-1}(CC_1^s \oplus C_1^s) = p_2(x)^{-1}(CC_2^s \oplus C_2^s)$$

and

$$M_2^t = p_1(x)^{-1}(CC_1^t \oplus C_1^t) = p_2(x)^{-1}(CC_2^t \oplus C_2^t).$$

Notice that  $CC_1^s = CC_1^t$  and  $CC_2^s = CC_2^t$ , we get that

$$M_2^s \oplus M_2^t = p_1(x)^{-1}(C_1^s \oplus C_1^t) = p_2(x)^{-1}(C_2^s \oplus C_2^t).$$

So the probability of  $X_1 = X_2$  is 1.

When the distinguisher queries  $\mathcal{E}(\cdot, \cdot)$ ,  $\mathcal{D}(\cdot, \cdot)$ , then  $C_1^t$  and  $C_2^t$  are two independently random strings. So the probability of  $X_1 = X_2$  is  $1/2^n$ .

From the above analysis, the advantage of the distinguisher is  $1 - 1/2^n$ .

### 3.2 One-query Distinguisher

This distinguisher only makes one encryption query. Notice that when the message length is  $m = n + 3$  blocks,  $p^{n+2}(x) = p^{n+3}(x) = 1 + x$ . We make an encryption query of  $(N, P_1, P_2, \dots, P_{m+3})$ , where  $P_1 = P_2 = \dots = P_{m+3} = 0^n$ , and get  $(C_1, C_2, \dots, C_{m+3})$ . If  $C_{n+2} = C_{n+3}$  then return 1, else return 0.

When the distinguisher queries  $\mathbf{E}(\cdot, \cdot)$ , we always have  $C_{n+2} = C_{n+3}$ . When the distinguisher queries  $\mathcal{E}(\cdot, \cdot)$ , the probability of  $C_{n+2} = C_{n+3}$  is  $1/2^n$ .

From the above analysis, the advantage of the distinguisher is also  $1 - 1/2^n$ .

## Acknowledgment

The authors would like to thank Debrup Chakraborty for providing their paper. It's a great pleasure to discuss your work with you.
